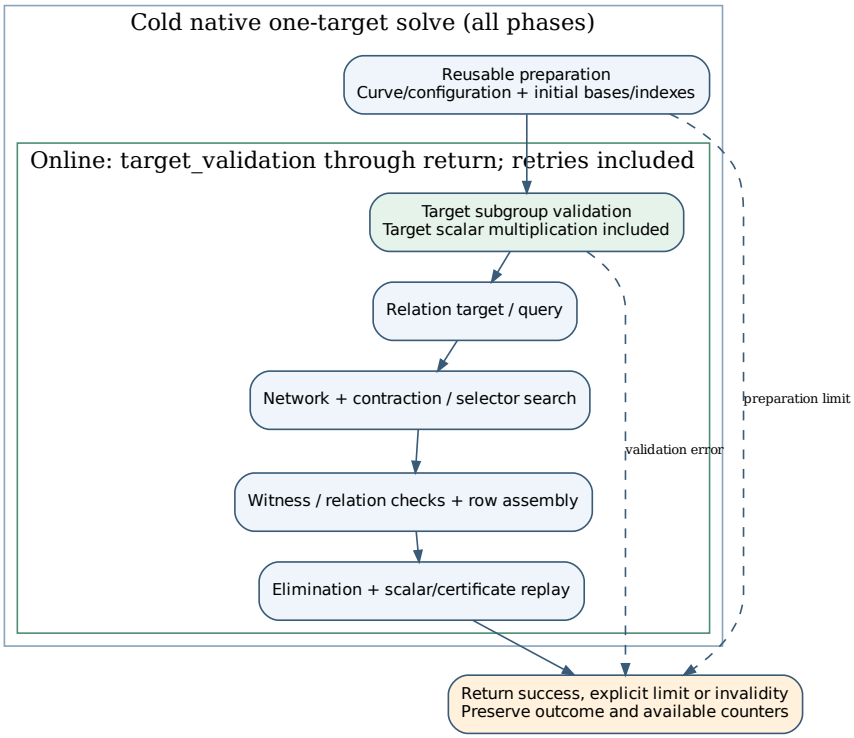
Native ECBench online boundary

Software correction and pre-data continuation – 2026-11-04

Target subgroup validation now begins the native online interval after initial reusable preparation. The previous ordering charged its scalar multiplication to setup. Source/selector/width and partial collection share the corrected boundary. Later retries and all internal replay stay inside online. [pcc:unverified]

The original-ordering regression fails on one scalar call left in setup; the corrected control requires zero there and one in target validation, and checks the full cold/online partition. Producer logs report 121 native tests in crypto and 98 in cryptanalysis, with format, strict lint and Rust 1.78 all-target checks. These are local development observations, without an independent signed verdict: PCC-20261104-9bb71e and PCC-20261104-0f6851. [pcc:unverified]



The original 1,728-attempt panel and frozen v1/v2 remain preserved. A new pre-data amendment binds current source and accounting. Current budget headroom, source publication, fresh S3 readback and authenticated exact-image admission precede any cloud build/measurement as applicable. Local test time is not the study's measurement. Unpriced arithmetic and observer overhead remain disclosed. [pcc:unverified]

Sources and custody. README.md links the pinned reduction, review thread, exact source manifests, original failure and corrected receipts, ECBench contract and current cost/PCC/benchmark-record rules. Editable diagram and report sources are beside this PDF. No runtime-gain result is reported.
