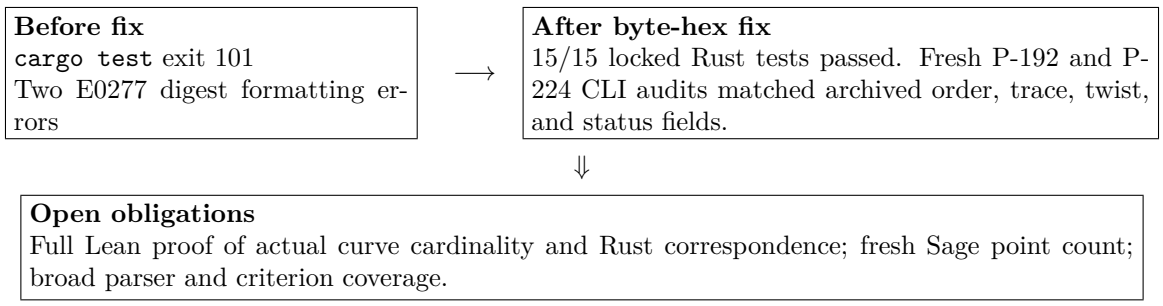
P-192 / P-224 curve audit: native Rust followup

27 October 2026 UTC. Conductor T-510 and T-511. The first locked build failed before tests ran because the pinned `sha2 0.11.1` digest array does not implement `LowerHex`. That exact failure is preserved.



Fresh execution and controls

Locked package test	Exit 0; 15 passed, 0 failed; known SHA-256 vector passed.
Locked binary build	Exit 0; exact built binary digest in the JSON receipt.
P-192 / P-224 CLI with exact certificates	Both exit 0; archived mathematical fields and verdict match.
P-192 without a certificate	Exit 0; supplied order remains `supplied_unverified`.
Altered P-192 input with original certificate	Exit 2; input-byte binding rejects it.

The fresh binary embeds a recomputed digest of its four Rust source files; both CLI outputs agree with an independent digest computation. The digest differs from the old producer because the source repair changed `main.rs`. The original Python replay remains separate. These tests validate the stated fixtures and selected failure paths, not all 61 criteria or a formal proof of the curve orders. The overall audit verdict for both curves is `incomplete_assessment`. No benchmark was run, so no performance plot or dashboard value changes.

Exact commands, timestamps, input and output hashes, stderr, stdout, and the comparison are in `report.md` and JSON receipts beside this PDF. The editable vector diagram is `validation-boundary.svg`.
