Derived recognition and remaining obligations; no instantiated attack or novelty claim
Ordinary E over F_(2^(3d)): y^2+xy=x^3+a*x^2+b
Compute rational roots of X^4+X^3+b
d odd: Tr(cube_root(b))=0, giving two roots
d even: four roots
Exact rational, coordinate-transverse 3-torsion condition
Explicit abstract module kernel, rank 3
Weighted pairing: J + qJ + q^2J
Frobenius stability and zero coordinate intersections
Additional hypotheses: d >= 2 and absolute degree(b)=3d
No degree 1 or 2 isogenies between conjugate factors
The principally polarized quotient is geometrically indecomposable
Arithmetic Torelli: a genus-three Jacobian for ONE twist
An isogeny with 3-primary kernel exists
Prime subgroups of order other than 3 survive
not supplied by the recognition test
Still needed: publication-priority audit, selected twist,
source torsion coordinates, target equation, evaluated isogeny
and independently verified planted-log transfer
