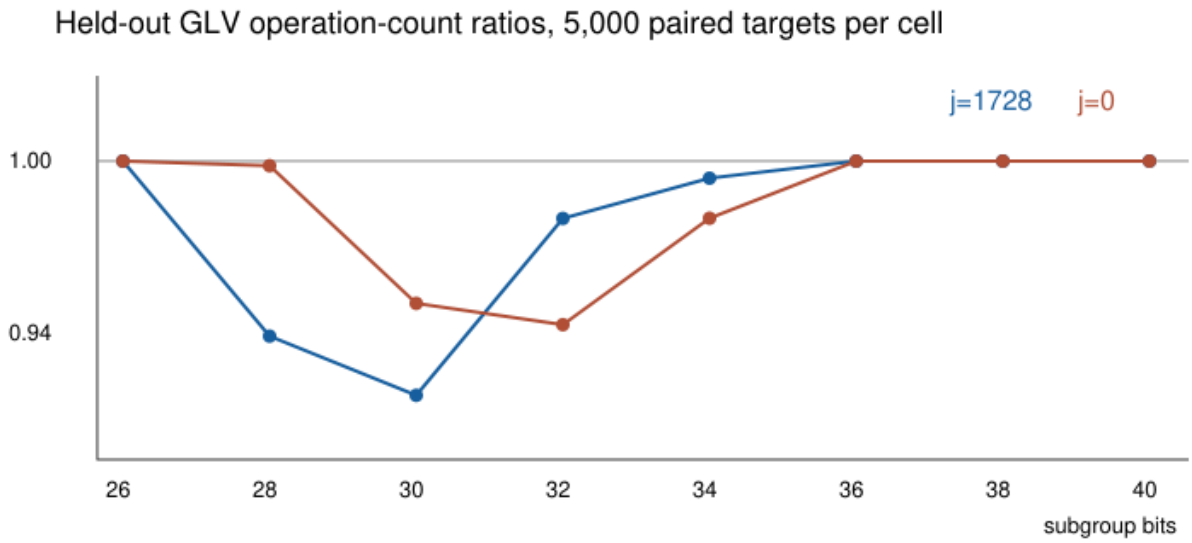
Independent GLV held-out raw-row audit

2026-11-07. Two content-addressed compressed row files matched their committed SHA-256 digests. An independent parser read 80,000 paired rows per arm, checked the full 2-family by 8-size by 200-curve by 25-target grid, and found 45,700 equal-table controls with zero count mismatches. All 16 cell point ratios and both primary geometric means match the published result to 10^{-15} absolute tolerance.

Family	Geometric mean	Independent 97.5% interval	Published interval
$j = 1728$	0.9565397206	[0.948088, 0.964908]	[0.948003, 0.964895]
$j = 0$	0.9670782595	[0.958173, 0.976202]	[0.958117, 0.976189]

The independent intervals use 10,000 curve-level resamples with a new seed. Endpoint differences are Monte Carlo variation; both upper bounds remain below one. The first PR commit `f630cc30` carried protocol, launcher, frozen analysis, and source before result commit `d433d5f9`. The commit order does not itself prove the first trial start time.



Scope. Operation-count ratios were recomputed from producer rows; correctness flags were only inspected. No native binary with the pinned digest was replayed, so the flags and counters lack an independent execution check. This run has no `experiment.export/v1` bundle, and no A/A arm was specified. The complete method, source hashes, and cell totals are in `REVIEW.md` and the adjacent scripts and JSON.
