CT26 Frobenius on the 7-kernel

Independent finite-field producer oracle • [pcc:unverified] • public toy curve

Selected kernels over F_101

E109

x^3 + 35x^2 + 100x + 72

Frobenius scalar: [5]

Point field: F_(101^6)

E113

(x-50)(x-68)(x-76)

Frobenius scalar: [6]

Point field: F_(101^2)

Full geometric 7-torsion, standard symplectic pairing

```
Spec(E109[7]) = {2,5};   Spec(E113[7]) = {4,6}
```

Exact finite linear-algebra audit

2850 rank-two planes → **400** max. isotropic → **4** rational isotropic

Of six Frobenius-stable planes, two are the full individual elliptic 7-torsion spaces and fail isotropy. The four surviving planes choose one Frobenius eigenline on each elliptic factor.

Geometric kernel input completed; Jacobian image still missing

The selected product kernel contains 49 points. The oracle verifies both seven-element group tables, all 49 product pairs, Frobenius closure and the eight cyclic lines. It has NOT evaluated any P0 pullbacks, genus-2 divisors, R1 or Psi.

Construction and limits

Uses an independently written F101^3 arithmetic engine, F101^6 square roots, elliptic group law and exhaustive reduced-row-echelon enumeration. One initial model failed because E113 kernel polynomial splits completely over F101. The correction preserves that negative result.

Source: cryptanalysis PR #1484; crypto PR #3877; HLP (math/9809210), section 3.2.

Reproduce: python3 -S -B experiments/chained-transfer-reference/ct26/seven_kernel_oracle.py

Pending: native P0(49), 64 four-torsion lifts, Richelot R1/Psi, signed PCC, complete cost.
